

User guide

How to use the Option Dashboard: what each screen shows, how the signals are calculated, and a practical playbook for selling option spreads on Nifty 50 stocks and NSE indices.

Everything here is a research aid, not advice. Option selling can lose much more than the premium you collect. Paper-trade first.

What this portal is

The portal helps you **sell option premium with defined risk**. It scans the indices and Nifty 50 stocks in your watchlist, tells you which direction is safer to sell against (using weekly and daily RSI), checks the chart for reasons the trend might reverse, and then helps you pick strikes, size the trade, and track it until it closes.

The idea in one line: **sell options on the side the market is moving away from, beyond a support or resistance level, 5–12% from the current price, with a hedge so the loss is capped.**

You make money when the stock stays below your sold call / above your sold put until expiry, as the option premium decays to zero.

Every number has a small ⓘ icon. Hover (or tap) it to see where the data comes from, when it was last fetched, and exactly how it is calculated.

The 4-step workflow

- 1 **Pick** — on the [Dashboard](#), filter for a clean signal (Bear Call, Bull Put or Iron Condor) with no results before expiry, and select a few names.
- 2 **Analyse** — press *Analyse selected*. Check the chart summary, reversal confluence and the support/resistance (S/R) chart for each stock.
- 3 **Build** — in the option chain, press *Suggest strikes* or pick your own with the S/B buttons. Make the validation checklist green and keep the margin inside the cap.
- 4 **Track** — press *Record position* (real) or *Paper trade*. Watch the % of stop used on the [Positions](#) page and close when your rules say so.

Step 1 — Dashboard (signal grid)

One card per instrument in your watchlist (indices first, then stocks roughly by Nifty 50 weight).

On the card	Meaning
Price & % change	Last price and change vs previous close (Yahoo, ~15 min delayed; indices FINNIFTY/MIDCPNIFTY from NSE).
Sector chip	Sector, used for filtering and for the sector-context chart.
Signal chip	The suggested structure from the RSI rule below.
W:xx D:xx	Weekly and daily RSI(14).
R / A / D / B badge	Corporate event between today and the next monthly expiry: R = results, A = AGM/EGM, D = dividend, B = bonus/split. Hover to see date and purpose.
n	Number of notes you've written for this stock.
☆ / ★	Add to / remove from your watchlist (use the ★ Watchlist filter).
Circle (right)	Selected for analysis. Click anywhere on the card to toggle.

How the signal is decided

RSI zones: **below 40 = bearish**, **above 60 = bullish**, **40–60 = neutral**. The **daily** RSI triggers the trade; the **weekly** RSI must not point the other way.

Daily RSI	Weekly RSI	Signal	What you'd sell
< 40	< 60 (bearish or neutral)	Bear Call	Call spread above the market
> 60	> 40 (bullish or neutral)	Bull Put	Put spread below the market
40–60	40–60	Iron Condor	Both — a call spread above and a put spread below
anything else		Wait for confirmation	Nothing yet — weekly is trending but daily hasn't confirmed, or they disagree

Filters

- **Events** — *No events* is the safest starting point; results days cause gaps that can jump past your strikes.
- **Signals** — show only one structure.
- **Sector chips** — avoid putting all trades in one sector.

- ★ **Watchlist** — only the stocks you starred.

The "**signals as of HH:MM**" stamp shows when data was last refreshed. **Refresh now** (top right) fetches new data; if the last refresh was under 2 minutes ago it simply shows the cached data.

Step 2 — Analysis page

One tab per selected symbol. Use the **Candle / Line** toggle (top right) for all price charts.

Header & chart summary

- **Weekly / Daily rows** — RSI value, which zone rule it meets, and the verdict (Bearish / Neutral / Bullish).
- **BB weekly / BB daily** — Bollinger Bands (20-period, 2 standard deviations): upper, middle, lower and their % distance from the current price (CMP). The bands are a natural "stretch" limit — strikes outside the weekly band are statistically harder to reach.
- **Prev month** — last month's high and low. These often act as support/resistance.
- **Confluence x/3** — how many reversal checks are firing (see below).

RSI charts

Weekly RSI (3 years) and daily RSI (2 years) with the 40 and 60 lines. Look at where RSI turned in the past — if the weekly has bounced from ~30 several times, a fresh Bear Call near 30 carries more reversal risk.

Reversal confluence

Three independent checks for signs the current move is ending. Each shows ✓ (active) or ✕:

Check	Fires when
Bollinger Bands	A daily close at/below the lower band (bullish exhaustion) or at/above the upper band (bearish exhaustion) in the last 3 sessions.
RSI divergence	Price made a lower low but RSI made a higher low (bullish), or price made a higher high but RSI a lower high (bearish) — within the last 20 bars. Older divergences are counted but don't fire.
Candlestick	A quality reversal candle (hammer, shooting star, engulfing, morning/evening star, piercing, dark cloud) in the last 10 days, after a move and near the outer band.

How to use it: 0/3 = the trend is intact, sell with the signal. 1/3 = be a little more conservative (further strikes). **2–3/3 pointing against your trade = skip it or wait.** Example: a Bear Call with a 2/3 bullish reversal means the stock may bounce into your short call.

Squeeze banner — when the Bollinger Bands move inside the Keltner Channels, volatility is compressed ("squeeze ON"); when they burst back out, the squeeze has **FIRED** and a large move usually follows. After a fired squeeze, place short strikes further away and size smaller.

The **What this means** box summarises the above in plain English.

Sector context

Monthly candles of the sector index (e.g. Nifty Oil & Gas for RELIANCE) with Bollinger Bands. Selling a Bear Call is more comfortable when the sector is also weak; be careful if the sector is strong while the stock is weak.

S/R analysis chart

- **Levels** come from swing highs/lows on daily, weekly and monthly charts, merged when within 0.3%. **Solid line** = touched 2+ times, **thick** = seen on more than one timeframe (stronger). Only levels within 12% of CMP are drawn; single-touch levels are listed in the legend (click a legend row to show/hide it).
- **Shaded 5–12% zone** — the option-selling zone above and below CMP.
- **Prev-month high/low** lines, **CMP** line, Bollinger Bands, and **unfilled gaps** $\geq 1.5\%$ (shaded boxes — price often comes back to fill them).
- **Your strikes** from the builder are drawn too (magenta = calls, cyan = puts) so you can see whether a level sits between the price and your short strike.
- Toggles: Daily / Weekly / Monthly candles, 2Y / 5Y history (levels are recomputed), zone on/off, all levels on/off. *Turning points* lists the dates each level was touched.

Notes & PDF

Keep a dated journal per stock ("results on 7th — trade after"). The dashboard shows a 📊 count.

Save as PDF prints the whole analysis.

Step 3 — Option chain & position builder

Live NSE option chain for the chosen expiry (stocks: monthly; indices: weekly + monthly). Columns per strike, calls on the left and puts on the right: **OI**, **ΔOI** (change today), **IV**, **Δ** (delta), **LTP**, and **S/B** buttons. Purple strikes are inside the 5–12% zone; amber cells are in-the-money; the ATM row is outlined.

Building a trade

- 1 **Validate as** — pick the structure (defaults to the RSI signal).
- 2 **Suggest strikes** — the portal sells the first strike just beyond the nearest S/R level inside the 5–12% zone with $\Delta \leq 0.30$, and buys a hedge two strikes further out. Treat it as a starting point.
- 3 Or click **S** on a premium to sell it and **B** to buy a hedge. Click again to remove. Edit price and lots in the legs panel.
- 4 Read the results: **net credit**, **max profit** (= credit), **max loss**, **breakeven(s)**, **POP**(probability of profit at expiry), **estimated margin** vs your cap, and the **payoff chart**.
- 5 Work through the **validation checklist** until it's green: matches the signal · each short leg hedged · short strikes in the 5–12% zone · short $\Delta \leq 0.30$ · a support/resistance level between CMP and your short strike · margin within cap · no event before expiry.
- 6 Press **Record position** → (real) or **Paper trade** → to carry the legs to Positions.

Margin shown is an **estimate** (hedged spread $\approx$ max loss + 10%; naked short $\approx$ SPAN + exposure % of notional). Your broker's number will differ — check it before placing the order. Greeks and POP are model values (Black-Scholes on NSE IV).

OI analytics

OI is shown in the same view as the chain: a summary strip above the table, and an OI bar on every strike row (calls grow left from the strike, puts grow right; darker bars are the call/put walls; ♦ marks max pain). Switch the bars between **Open interest** and **Change in OI**.

Item	How to read it
PCR (OI)	Put OI ÷ call OI. Below 0.7 = call-heavy (writers expect a cap above → bearish tilt). Above 1.3 = put-heavy (support below → bullish tilt). In between = balanced.
PCR (volume)	Same ratio on today's traded volume — a faster, noisier read.
Max pain	The strike where option buyers lose the most at expiry; price often drifts toward it in the last days.
ATM IV	Implied volatility at the money. Higher IV = richer premiums but bigger expected moves.
Call wall / Put wall	Strikes with the highest call / put OI — option writers' resistance and support. Placing your short strike beyond a wall adds protection.
OI bars (in the chain)	Calls left (red), puts right (green) on each strike row. Switch to Change in OI to see where fresh positions were added today. Hover a bar for its build-up type.

Build-up types (price change + OI change): Long build-up (↑ price, ↑ OI), Short build-up (↓ price, ↑ OI), Short covering (↑ price, ↓ OI), Long unwinding (↓ price, ↓ OI).

Step 4 — Positions & ROI

Two books: **Real** (your actual trades) and **Paper** (practice). Both work the same way.

Recording

- Arrives prefilled from the builder, or click + **New position**, type a symbol and **Load expiries & suggest**(fills expiry and lot size, and prefills the recommended strikes with live premiums). Changing the strategy refills the legs for that strategy; changing a strike fetches its premium. A price that looks like a strike is flagged and blocks saving.
- Enter **lots**, **capital** and **risk % per trade**, choose a **stop rule**, check the legs, and Save.
- The readout shows the net credit and the loss at your stop, and warns if that exceeds capital × risk %.

Stop rules

Rule	Stop is hit when
1:1 — 1× credit	Your loss equals the credit received (tight).
1:2 — 2× credit	Loss = 2× the credit.
1:3 — 3× credit	Loss = 3× the credit (default; gives the trade room).
Strike breach	The underlying comes within 0.5% of a short strike, regardless of P&L.

Open position cards

- **P&L** (live from the NSE chain) and per-leg P&L.
- **% of stop used** bar — green → amber (50%) → orange (80%) → red (100%). The card border turns red at 95%.
- **POP now / at entry** — if POP has dropped more than 10 points, it turns red: the trade has moved against you.
- Breakevens, margin, spot and its move since entry, and how far the nearest short strike is.
- **Close** (enter realised P&L — prefilled with current P&L), **Close legs** (exit one side of an Iron Condor; credit, max loss and stop are recalculated for what's left), **Edit entry**, **Delete**.

Tags: **LIVE** during market hours, **AS OF CLOSE** after 15:30 and at weekends, **AT PREV CLOSE** before 09:15.

ROI

Monthly and annual tables: margin used, realised (positions closed that month), unrealised (open positions, counted in the current month), total, and **ROI = total ÷ margin**. Brokerage and taxes are not included.

Strategy playbook

These are commonly used guidelines that fit the portal's checks — not guarantees. Adapt them to your own risk tolerance and test on the Paper book first.

Bear Call spread — when the signal is Bear Call

- **Sell** a call 5–12% above CMP, beyond the nearest resistance level (ideally also beyond the call wall or the weekly upper BB).
- **Buy** a higher call (1–3 strikes further) as the hedge — this caps your loss.
- Profit if the stock stays below the short call at expiry. Max profit = credit; max loss = strike gap – credit.
- Avoid if reversal confluence is 2/3+ bullish, or a results date falls before expiry.

Bull Put spread — when the signal is Bull Put

- **Sell** a put 5–12% below CMP, beyond the nearest support (ideally beyond the put wall / weekly lower BB).
- **Buy** a lower put as the hedge.
- Profit if the stock stays above the short put. Avoid if reversal confluence is 2/3+ bearish.

Iron Condor — when the signal is Iron Condor (both RSIs 40–60)

- A Bear Call above **and** a Bull Put below, same expiry. You collect two credits; only one side can lose at expiry.
- Best when the stock is range-bound: price near the BB middle, no squeeze firing, PCR balanced.
- If one side is threatened, close that side with **Close legs** and keep the other.

Wait for confirmation

Don't force a trade. Revisit in a few days — the daily RSI often catches up with the weekly.

Choosing strikes — quick checklist

- 1 5–12% from CMP (purple strikes in the chain).
- 2 At least one drawn S/R level between CMP and your short strike.
- 3 Short-strike delta ≤ 0.30 (roughly $\leq 30\%$ chance of finishing in the money).
- 4 Beyond the call/put wall if possible.
- 5 Credit worth the risk — as a rough guide, credit of at least ~15–20% of the strike gap.
- 6 Margin within 20% of capital; loss at stop within your risk % per trade.

Managing the trade (common practice)

- **Take profit early** — many sellers close at 50–70% of max profit rather than holding to expiry.
- **Respect the stop** — when % of stop used reaches 100% (or the strike-breach stop fires), exit; don't hope.
- **Watch events** — close or avoid positions over results days.
- **Expiry week** — gamma risk rises sharply; consider closing a few days before expiry if the short strike is close.

Risk management rules

- **Margin cap:** each position's margin $\leq 20\%$ of capital (default capital ₹1,00,000 → cap ₹20,000).
- **Risk per trade:** loss at stop $\leq \text{capital} \times \text{risk \%}$ (default 1%).
- **Always hedge:** a naked short option has unlimited loss — the builder flags it.
- **Diversify:** spread trades across sectors and directions; don't open five Bear Calls in one sector.
- **Paper first:** run the Paper book for a few expiries before trading real money.

Daily / weekly routine

When	What to do
Before 09:15	Positions shows AT PREV CLOSE values. Review notes and any events today.
After the open (~09:30+)	Refresh. Check Positions — anything above 50% of stop? Any short strike within ~2%?
Entry days	Dashboard → filter No events + a signal → Analyse 3–5 names → build, validate, record.
Intraday	Data refreshes every 15 min automatically; use Refresh now when needed.
After 15:30	AS OF CLOSE values. Update notes; close or adjust per your rules.
Month end	Check the ROI table; review closed trades and what worked.

Data sources, refresh & limits

Data	Source	Delay
Stock, NIFTY, BANKNIFTY candles & prices	Yahoo Finance (free)	~15 min
Option chains, OI, IV, expiries, lot sizes	NSE website (free)	~1–3 min; cached 60 s
FINNIFTY, MIDCPNIFTY, sector indices	NSE website	end of day + live index board
Corporate events (R/A/D/B)	NSE event calendar & corporate actions	once a day
Greeks, POP, margin, S/R, signals	Calculated by the portal	—

- **Auto-refresh** every 15 minutes during market hours (09:15–15:30), plus once after the close.
- **Optional Angel One** — add SmartAPI keys to `.env` for live prices (and, later, exact margins).
- **Limits:** margins are estimates; Greeks/POP are model values; P&L excludes charges; NSE may block cloud servers, so a VPS setup may need Angel One.

Changing settings

Two plain-text files in the `OPTIONDASHBOARD/config` folder (changes apply on the next refresh):

File	What you can change
<code>watchlist.yaml</code>	Which indices/stocks are tracked (enabled: true/false), their order, sector and number of expiries. Fewer symbols = fewer data calls.
<code>settings.yaml</code>	RSI period and the 40/60 thresholds, refresh interval, default capital, margin cap %, risk % per trade, margin-estimate percentages, sector-index mapping.

Glossary

Term	Meaning
CMP	Current market price of the stock or index.
CE / PE	Call option / put option.
Strike	The price at which the option can be exercised.
OTM / ITM / ATM	Out of / in / at the money. A call is OTM when its strike is above CMP; a put when below.
Premium / LTP	The option's price (last traded price).
Credit spread	Sell one option and buy a further-OTM one: you receive a net credit and your loss is capped.
Hedge	The bought option in a spread that limits loss.
Lot size	Number of shares per contract (e.g. RELIANCE 500). P&L = price change × lot size × lots.
RSI	Relative Strength Index (0–100), a momentum gauge. Below 40 weak, above 60 strong (portal thresholds).
Bollinger Bands	A 20-period average ± 2 standard deviations; marks how stretched price is.
Keltner Channel / squeeze	An ATR-based channel; Bollinger Bands inside it = squeeze (low volatility before a big move).
Support / resistance	Price levels where the stock has turned before.
OI	Open interest — number of outstanding contracts.
PCR	Put-call ratio of OI (or volume).
Max pain	Strike where option holders lose the most at expiry.
IV	Implied volatility — the market's expected annualised move, priced into premiums.
Delta	How much the option price moves per ₹1 move in the stock; also a rough probability of expiring ITM.
POP	Probability of profit at expiry, from a lognormal model using IV.
Breakeven	The underlying price at expiry where the trade makes zero.
Margin	Money the broker blocks to hold the position.

Term	Meaning
Expiry	Last trading day of the contract (NSE monthly: last Tuesday, shifted for holidays).

FAQ

▼ Why are prices different from my broker?

Prices come from free sources: Yahoo is ~15 minutes delayed and NSE ~1–3 minutes. Always confirm the live premium in your broker before placing an order.

▼ The option chain says 'unavailable'.

NSE occasionally rate-limits or blocks requests. Wait a minute and press ↺. On a cloud server NSE may block access entirely.

▼ Why is the margin different from my broker's?

The portal estimates margin. Brokers use exact SPAN files and their own add-ons. Treat the portal figure as a guide.

▼ A stock I want isn't on the dashboard.

Add it to `config/watchlist.yaml` (it must be in NSE F&O) and press Refresh now.

▼ Can I trade from the portal?

No — it's for analysis and tracking. Place orders in your broker, then record them here.

▼ What does 'Wait for confirmation' mean?

Weekly and daily RSI don't agree yet. Skip the stock for now.
